

Fried Chips are Overrated

Nothing will dampen your retro fun quicker than an electrostatic *jolt* from your hand or from an I/O port connector. Chips that tend to be the most vulnerable to ESD impact are the SID which controls your sound and the CIAs which control all of your input and output operations (e.g., keyboard, disk drive, dataset, timers, etc.).

Luckily, EVO has you covered, with a set of fully integrated ESD protection chips, which are strategically placed near the primary I/O cable inputs. Any static charges will be immediately grounded, which protects your precious system and preserves those increasingly difficult to replace MOS chips... ***Oh, you're welcome!***
